Do not hesitate to contact us if you have any problems.[Therapeutic strategy in the management of isolated lung metastasis of esophageal carcinoma]. Sixteen cases of isolated lung metastasis of the esophageal carcinoma treated between 1984 and 1990 were analyzed. Two operative procedures were done, i.e. a thoracotomy and an extended lymph node dissection. In the other 14 cases, radiation therapy was performed. A total of 24 lung metastases were detected in our series. Among the 16 operative cases, two patients who had metastases greater than 2 cm in diameter survived more than 5 years without any signs of recurrence. The other 14 operative cases showed a median survival period of 11 months with a recurrence rate of 57% (8 of 14). In contrast, radiation therapy was effective in 14 of the 16 patients with a median survival time of 16 months and a recurrence rate of 19% (3 of 16). The difference in the recurrence rates between the two groups was significant. We believe that our data supports the hypothesis that extended surgery for primary tumors, which includes the removal of the primary lung lesions and the lymph nodes in the chest wall and aortopulmonary ligament, is more effective than simple radiation therapy in the management of isolated lung metastasis of the esophageal carcinoma.'Safe Spaces' aren't safe for f988f36e3a
